³Graz University of Technology

Side-Channel Attacks on Hash Functions?

- Plain hashing has no secrets, but there are keyed uses
 - HMAC? Classic DPA setting, threat is obvious. . .
- Keccak (SHA3/SHAKE) found ample new uses involving secrets
 - . . . especially in post-quantum cryptography

Side-Channel Attacks on Hash Functions?

- Keccak uses in PQC include
 - derivation of a shared secret in a KEM
 - expansion of a secret seed in KEMs and signatures
 - hash-based signatures
- Above: side-channel attacker is limited to a single execution
 - at most averaging, but still no DPA

Are attacks even possible? Are countermeasures still needed?

- Practical single-trace attack on Keccak (software) implementations
- Soft-analytical side-channel attack (SASCA)
 1. Template matching: retrieve probabilities of intermediates
 2. Belief propagation: combine all probabilities to infer most likely key
 - thus far: mainly applied to AES, but Keccak structurally very different
- Attack outcome
 - key-recovery in a large array of settings, countermeasures cannot be omitted
 - factors influencing the success rate:
 - key size, bit width of device, structure of input

- Sponge construction, 1600-bit state

- Sponge construction, 1600-bit state
- Keccak- f permutation

- Sponge construction, 1600-bit state
- Keccak- f permutation
 - θ - add column parities

- Sponge construction, 1600-bit state
- Keccak- f permutation
 - θ - add column parities
 - ρ - rotate lanes

- Sponge construction, 1600-bit state
- Keccak- f permutation
 - θ - add column parities
 - ρ - rotate lanes
 - π - reorder lanes

- Sponge construction, 1600-bit state
- Keccak- f permutation
 - θ - add column parities
 - ρ - rotate lanes
 - π - reorder lanes
 - χ - SBox

- Sponge construction, 1600-bit state
- Keccak- f permutation
 - θ - add column parities
 - ρ - rotate lanes
 - π - reorder lanes
 - χ - SBox
 - ι - add round constant

Attack Setting

- Unprotected software implementation on a μC
- (Part of) the input is secret
 - and used only once
- Power measurements of a single execution
 - no differential SCA
 - have to use (some sort of) templates

Template Attacks on Hash Functions

- Typical restrictions of template attacks
 - need templating device with known key
 - poor portability of templates between devices
- Same for Keccak?
 - often multiple calls inside a PK scheme, some with fully known data
 - message hash during signing, re-encryption in decapsulation, ...

Profiling directly on target device!

no separate profiling device needed, no portability problems

Step 1: Template Matching

- Templating target: all loads/stores
 - HW leakage along lanes
 - assign probability vector to each part

- Now: combine all side channel info to find most likely key
 - efficient method: Soft Analytical Side-Channel Attacks (SASCA)
[Veyrat-Charvillon et al., ASIACRYPT 2014]

Step 2: SASCA / Belief Propagation

1. model implementation as a *factor graph*

- variable nodes
- factor nodes
- example: $X \oplus Y = Z$

Step 2: SASCA / Belief Propagation

1. model implementation as a *factor graph*
 - variable nodes
 - factor nodes
 - example: $X \oplus Y = Z$
2. incorporate leakage information in graph

Step 2: SASCA / Belief Propagation

1. model implementation as a *factor graph*
 - variable nodes
 - factor nodes
 - example: $X \oplus Y = Z$
2. incorporate leakage information in graph
3. run *Belief Propagation*
 - goal: find marginals of variables
 - message passing principle
 - simplest version: enumerate inputs
 - important: avoid circular reasoning

Step 2: SASCA / Belief Propagation

1. model implementation as a *factor graph*
 - variable nodes
 - factor nodes
 - example: $X \oplus Y = Z$
2. incorporate leakage information in graph
3. run *Belief Propagation*
 - goal: find marginals of variables
 - message passing principle
 - simplest version: enumerate inputs
 - important: avoid circular reasoning

Step 2: SASCA / Belief Propagation

1. model implementation as a *factor graph*

- variable nodes
- factor nodes
- example: $X \oplus Y = Z$

2. incorporate leakage information in graph

3. run *Belief Propagation*

- goal: find marginals of variables
- message passing principle
- simplest version: enumerate inputs
- important: avoid circular reasoning

Step 2: SASCA / Belief Propagation

1. model implementation as a *factor graph*
 - variable nodes
 - factor nodes
 - example: $X \oplus Y = Z$
2. incorporate leakage information in graph
3. run *Belief Propagation*
 - goal: find marginals of variables
 - message passing principle
 - simplest version: enumerate inputs
 - important: avoid circular reasoning

Step 2: SASCA / Belief Propagation

1. model implementation as a *factor graph*
 - variable nodes
 - factor nodes
 - example: $X \oplus Y = Z$
2. incorporate leakage information in graph
3. run *Belief Propagation*
 - goal: find marginals of variables
 - message passing principle
 - simplest version: enumerate inputs
 - important: avoid circular reasoning

Step 2: SASCA / Belief Propagation

1. model implementation as a *factor graph*

- variable nodes
- factor nodes
- example: $X \oplus Y = Z$

2. incorporate leakage information in graph

3. run *Belief Propagation*

- goal: find marginals of variables
- message passing principle
- simplest version: enumerate inputs
- important: avoid circular reasoning

A First Factor Graph of Keccak

- Bitwise description
 - each bit after each step is a variable
- Terrible performance. . .
 - leakage on bytes/words, not bits
 - lots of information lost during propagation

Solution: Clustering

- Cluster multiple bits in a single variable node
 - bits along a lane
 - ideally: no spreading of side-channel info
- Cluster size vs. resource usage
 - runtime and memory: exp. in cluster size
 - we support 8-bit and 16-bit clusters

Clustering: Misalignment

- Problem: misalignment of clusters
 - previous SASCA on AES: operations on bytes
 - Keccak operations not aligned
- Example: $A \oplus \text{ROT}(B, 4)$
- Need to split clusters
 - requires extraction of marginals

- Computation of column parity
 - 5-input \oplus node (efficient propagation)
 - enumeration of all possible values: 2^{40} (8-bit cluster)
 - solution: fast convolution of distributions using Walsh-Hadamard transform

Clustering: Further Considerations

- Handling χ
 - break up clusters to deal with invertability

Clustering: Further Considerations

- Handling χ
 - break up clusters to deal with invertability
- Handling 32-bit leakage
 - found efficient method to combine leakage
 - convolution instead of enumeration

- Open-source Python implementation of BP on Keccak
<https://github.com/keccaksasca/keccaksasca>
- Restriction to first two rounds of Keccak- f
- Runtime per BP iteration (updating all nodes once)
 - 8-bit clusters: \sim seconds on single core
 - 16-bit clusters: \sim 1 minute using 44 cores
 - 8-bit clusters sufficient in most cases
- BP: iterative algorithm, repeat until convergence.
 - typically < 10 iterations

- Goal: recover secret input of Keccak- f
- Evaluation tool: leakage simulations
 - noisy HW-leakage of loads/stores (at typical locations)
 - for 8, 16, and 32-bit implementations
 - vary noise σ , retrieve success rate
- Analyze impact of key size
 - evaluate 128 and 256-bit keys

On the Impact of the Input State

- Keccak- f input: part secret, part known
- Content of public part impacts success rate!
- *All-zero public input*
 - state = secret || 0000...
 - example: SHAKE(128-bit seed)
- *Random public input*
 - state = secret || rand
 - example: H(msg || key)
- Attacks with *Random public input* work much better!

But why though?

- Reason: \oplus of θ -effect T
- Observation: knowing T allows key recovery

But why though?

- Reason: \oplus of θ -effect T
- Observation: knowing T allows key recovery
- *All-zero public input*
 - T added 4 times to 0
 - same operation 4 times, averaging

But why though?

- Reason: \oplus of θ -effect T
- Observation: knowing T allows key recovery
- *All-zero public input*
 - T added 4 times to 0
 - same operation 4 times, averaging
- *Random public input*
 - T added to 4 different values
 - similar to a DPA using 4 traces

Results: 8-bit Device

8-bit HW leakage, real $\sigma \approx 0.5$ (XMEGA128D4)

Random public input

All-zero public input

Results: 16-bit Device

16-bit HW leakage, real $\sigma \approx ?$

Random public input

All-zero public input

32-bit HW leakage, real $\sigma \approx 0.4 - 3$ (STM32F303)

Single-trace attacks are a considerable threat ...

- especially for 8/16-bit implementations, situation less clear for 32-bit devices

But ...

- we used a simple leakage model (simulations with univariate HW templates)
- more sophisticated attacker will fare better (remember: on-device profiling)

Must always include (basic) countermeasures ...

- hiding (shuffling, dummy operations, etc.) effective
- masking also an option, but some restrictions
